## Convex sets and functions

### Definitions

Thanks: Much of this material is borrowed/copied from Ryan Tibshirani.

Set  $C$  is *convex* iff  $\forall x, c \in C, \forall t \in [0; 1] \quad tx + (1 - t)y \in C$ .

So  $C$  is convex iff for any two points in  $C$  their segment is also entirely in  $C$ .

*Convex combination* of set of points  $x_1, \dots, x_k \in \mathbb{R}^n$  is

$$\left\{ \sum_{i=1}^k \Theta_i x_i : \sum_{i=1}^k \Theta_i = 1, \forall i \Theta_i \in [0; 1] \right\}.$$

*Convex hull* of any  $C \in \mathbb{R}^n$ , denoted  $\text{conv}(C)$  is a union of all convex combinations of different elements of  $C$ .

### Some examples

- Empty set, point, line, segment.
- Norm ball:  $\{x : \|x\| < r\}$ .
- Hyperplane  $\{x : a^\top x = b\}$ , Affine space  $\{x : Ax = b\}$ .
- Hyperspace:  $\{x : a^\top x \leq b\}$ , Polyhedron  $\{x : Ax \leq b\}$ .
- Cone such that if  $x_1, x_2 \in C$  then  $t_1 x_1 + t_2 x_2 \in C \forall t_1, t_2 \geq 0$ .

### Cones

Set  $C$  is a *cone* iff  $\forall t \geq 0, x \in C \implies t^\top x \in C$ .

Type of cones:

- Norm cone:  $\{(x, t) : \|x\| \leq t\}$ .
- Normal cone for some  $C$  and  $x \in C$ :  $N_C(x) = \{g : g^\top x \geq g^\top y \forall y \in C\}$ .
- Positive semidefinite cone  $S_+^n = \{x \in S^n : x \succeq 0\}$ ,  $S^n$  is Hilbert space.

### Key properties of convex sets

- Separating hyperplane.  $A, B$  are convex, nonempty, disjoint. Then  $\exists a, b : A \subseteq \{x : a^\top x \leq b\}, B \subseteq \{x : a^\top x \geq b\}$ .
- Supporting hyperplane.  $C$  nonempty, convex,  $x_0 \in \text{boundary}(C)$ . Then  $\exists a : C \subseteq \{x : a^\top x \leq a^\top x_0\}$ .

## Operations preserving convexity

- Intersection.
- Scaling, translation.  $C$  is convex  $\implies aC + b$  is convex.
- Affine image and preimage.  $f(x) = Ax + b$ ,  $C$  is convex  $\implies f(C), f^{-1}(C)$  are convex.
- Lots more (See (Boyd and Vandenberghe 2004), chapter 2).

$A_1, \dots, A_k, B \in \mathbb{S}^n$  – symmetric matrices. Then  $C = \left\{ x \in \mathbb{R}^k : \sum_{i=1}^k x_i A_i \preceq B \right\}$ .

$f : \mathbb{R}^k \rightarrow \mathbb{S}^n$ ,  $f(x) = B - \sum_{i=1}^k x_i A_i$ .  $C = f^{-1}(S_+^n)$  – affine preimage of convex cone.

## Convex functions

Function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is *convex* iff  $\text{dom}(f) \subseteq \mathbb{R}^n$  is convex and

$$\forall x, y \in \text{dom}(f), t \in [0; 1] \quad f(tx + (1-t)y) \leq tf(x) + (1-t)f(y)$$

Other definitions:

- $f$  is *concave* iff  $-f$  is convex.
- $f$  is *strictly convex* iff  $\forall t \in (0; 1)$  the inequality in definition is strict.
- $f$  is *strongly convex* with parameter  $\tau$  iff  $f(x) - \frac{\tau}{2} \|x\|_2^2$  is convex.

## Examples

- $f(x) = \frac{1}{x}$  is strictly convex, but not strongly.
- Univariate functions:
  - $e^{ax}$  is convex  $\forall a \in \mathbb{R}$  over  $\mathbb{R}$ .
  - $x^a$  convex given  $a \geq 1$  or  $a \leq 0$  over  $\mathbb{R}_+$ .
  - $\log x$  is concave over  $\mathbb{R}_+$ .
- Affine  $a^\top x + b$  is both convex and concave.
- Quadratic  $\frac{1}{2}x^\top Qx + b^\top x + c$  is convex if  $Q \succeq 0$ .
- $\|u - Ax\|_2^2$  convex since  $A^\top A \succeq 0$ .
- Norms: all vector norms and most matrix norms are convex.
- Indicator function is convex.  $C$  is a convex set, then  $I_C(x) = \begin{cases} 0, & x \in C \\ \infty, & \text{otherwise} \end{cases}$ .
- Support function is convex  $\forall C$ .  $I_C^*(x) = \max_{y \in C} x^\top y$ .

## Key properties

- $f$  is convex iff its epigraph is convex, where  $\text{epi}(f) = \{(x, t) \in \text{dom}(f) \times \mathbb{R} : f(x) \leq t\}$ .
- $f$  is convex  $\implies$  all its sublevel sets are convex.  $C_t = \{x \in \text{dom}(f) : f(x) \leq t\}$ . The converse is false.
- Assume  $f$  is differentiable. Then  $f$  is convex iff  $\text{dom}(f)$  is convex and  $\forall x, y \in \text{dom}(f) \quad f(y) \geq f(x) + \nabla f(x)^\top (y - x)$ . Essentially, it means that  $f$ 's graph is above any tangent plain.
- Assume  $f$  is twice differentiable.  $f$  is convex iff  $\text{dom}(f)$  is convex and  $\forall x \in \text{dom}(f) \quad \nabla^2 f(x) \succeq 0$ .

## Operations preserving function convexity

- Nonnegative linear combination.
- Pointwise maximum.  $\forall s \in S \quad f_s$  is convex  $\implies f(x) = \max_S f_s(x)$  is also convex.
- Partial minimum.  $g(x, y)$  convex over variables  $x, y$ ;  $C$  convex. Then  $f(x) = \min_{y \in C} g(x, y)$  is also convex.  
E.g.,  $f(x) = \max_{y \in C} \|x - y\|$  or  $f(x) = \min_{y \in C} \|x - y\|$ .

## Terminology

### Optimization problem

A convex optimization problem (program)

$$\begin{aligned} & \min_{x \in D} f(x) \\ & \text{subject to} \quad g_i(x) \leq 0 \quad \forall i \in [1 : m] \\ & \quad \quad \quad Ax = b \end{aligned} \tag{1}$$

where  $f, g_i$  are convex and  $D = \text{dom}(f) \cap \text{dom}(g_i)$ .

### Terms

$$\begin{aligned} & \min_{x \in D} f(x) \\ & \text{subject to} \quad g_i(x) \leq 0 \quad \forall i \in [1 : m] \\ & \quad \quad \quad Ax = b \end{aligned} \tag{2}$$

- $f$  – criteria or objective function.
- $g_i$  – inequality constraints.
- $x$  is a *feasible point* if it satisfies the conditions, namely  $x \in D$ ,  $g_i(x) \leq 0$ , and  $Ax = b$ .
- $\min f$  over feasible points – *optimal value*  $f^*$ .
- If  $x$  is feasible and  $f(x) = f^*$  then  $x$  is an *optimum* (solution, minimizer).
- Feasible  $x$  is a *local optimum* if  $\exists R > 0$  such that  $\forall y \in B_R(x) \quad f(x) \leq f(y)$ .
- If  $x$  is feasible and  $f(x) \leq f^* + \varepsilon$  then  $x$  is  *$\varepsilon$ -suboptimal*.
- If  $x$  is feasible and  $g_k(x) = 0$  then  $g_k$  is *active* at  $x$  (otherwise inactive).

## Properties

- Solution set  $X_{opt}$  is convex.
- If  $f$  is strictly convex then the solution is unique.
- For convex optimization problems all local optima are global.
- The set of feasible points is convex.

## Example: Lasso.

$$\min_{\beta} \|y - X\beta\|_2^2 \text{ subject to } \|\beta\|_1 \leq s.$$

- $g_1(\beta) = \|\beta\|_1 - s$  - convex, no equality constraints.
- $X$  is  $n \times p$  matrix
  - If  $n \geq p$  and  $X$  is full rank then  $\nabla^2 f(\cdot) = 2X^T X$  is positive definite matrix. The function is strictly convex, therefore the solution is unique.
  - If  $p > n$  then  $\exists \beta \neq 0$  such that  $X\beta = 0 \implies$  multiple solutions.

## First Order Condition

- convex problem with differentiable  $f$
- a feasible  $x$  is optimal iff  $\nabla f(x)^T(x - y) \geq 0, \forall$  feasible  $y$
- if unconstrained, the condition reduces to  $\nabla f(x) = 0$

$$\min_x \frac{1}{2} x^T Q x + b^T x + c, \quad Q \succeq 0$$

- FOC:  $\nabla f(x) = Q^T x + b = 0$
- if  $Q \succ 0 \rightarrow x^* = -Q^{-1}b$
- if  $Q$  singular,  $b \notin \text{Col}[Q] \rightarrow$  no solution
- if  $Q$  singular,  $b \in \text{Col}[Q] \rightarrow x^* = -Q^* b + z$  with  $z \in \text{null}[Q]$

Projection onto convex  $C$  :

$$\min_x \|a - x\|_2^2 \quad \text{s.t.} \quad x \in C$$

$$\text{-FOC : } \nabla f(x)^T(y - x) = (x - a)^T(y - x) \geq 0, \forall y \in C \Leftrightarrow a - x \in N_2(x)$$

## Useful operations

### Partial optimization

Recall:  $h(x) = \min_{y \in C} f(x, y)$  is convex if  $f$  is convex, and  $C$  is convex.

$$\begin{aligned} \min_{x_1, x_2} \quad & f(x_1, x_2) & \min_{x_1} \quad & \tilde{f}(x_1) \\ \text{s.t.} \quad & g_1(x_1) \leq 0 & \iff \text{s.t.} \quad & g_1(x_1) \leq 0 \\ & g_2(x_2) \leq 0 & & \end{aligned} \tag{3}$$

where  $\tilde{f}(x_1) = \min \{f(x_1, x_2) : g_2(x_2) \leq 0\}$ .

- The right problem is convex if the left is (and vice versa)

## Transformations

- We can use a monotone increasing transformation  $h : \mathbb{R} \rightarrow \mathbb{R}$ :

$$\min_{x \in C} f(x) \Rightarrow \min_{x \in C} h(f(x))$$

- We can use a change of variable transformation  $\phi : \mathbb{R}^n \Rightarrow \mathbb{R}^m$  :

$$\min_{x \in C} f(x) \Leftrightarrow \min_{\phi(y) \in C} f(\phi(y))$$

**Example:** Geometric Program

$$\min_{x \in C} f(x) = \sum_{k=1}^p \gamma_k x_1^{a_{k1}} x_2^{a_{k2}} \dots x_n^{a_{kn}} \quad (\text{posynomial})$$

- $C$  : involves (convex) inequalities in some form and equalities are affine.
- We can change above non-convex problem to the following convex problem by letting  $y_i = \log x_i$

## Eliminate equality constraints

$$\begin{aligned} \min_x \quad & f(x) \\ \text{s.t.} \quad & g_i(x) \leq 0 \\ & Ax = b \end{aligned} \tag{4}$$

- $x$  feasible means  $\exists M : \text{col}[M] = \text{null}[A]$  and  $x_0 \text{ s.t. } Ax_0 = b$
- Let  $x = My + x_0$

Then the following is an equivalent problem:

$$\begin{aligned} \min_y \quad & f(My + x_0) \\ \text{s.t.} \quad & g_i(My + x_0) \leq 0 \end{aligned} \tag{5}$$

## Introduce slack variables

$$\begin{aligned} \min_x \quad & f(x) \\ \text{s.t.} \quad & g_i(x) \leq 0 \\ & Ax = b \end{aligned} \tag{6}$$

- Can add equality constraints:

$$\begin{aligned} \min_{x,s} \quad & f(x) \\ \text{s.t.} \quad & g_i(x) + s_i = 0 \\ & s_i \geq 0 \\ & Ax = b \end{aligned} \tag{7}$$

- But this is nonconvex unless  $g_i$  are affine

## Relaxation

We can relax nonaffine constraints

$$\min_{x \in C} f(x) \Rightarrow \min_{x \in \tilde{C}} f(x)$$

with  $C \subset \tilde{C}$

- In this case optimum of new problem is smaller or equal to the optimum of the original problem.

## Standard problems (with examples)

### LP (Linear Programs)

$$\min_x c^T x$$

with affine constraints

- Basis Pursuit  
 $\min_{\beta} \|\beta_0\| \text{ s.t. } X\beta = y$
- Above problem can be relaxed to :  
 $\min_{\beta} \|\beta\|_1 \text{ s.t. } X\beta = y.$
- This relaxation can be reformulated to a LP problem:  
 $\min_{\beta, z} 1^T z \text{ s.t. } z \geq \beta, z \geq -\beta, X\beta = y$
- Dantzig selector  
 $\min_{\beta} \|\beta\|_1 \text{ s.t. } \|x^T(y - X\beta)\|_{\infty} \leq \lambda$

### QP (Quadratic program)

Lasso, ridge regression, OLS, Portfolio Optimization

### SDP (Semi-Definite program)

$$\begin{aligned} \min_{X \in S_n} \quad & \text{tr}(C^T X) \\ \text{s.t.} \quad & \text{tr}(A_i^T X) = b_i \\ & X \succeq 0 \end{aligned} \tag{8}$$

### Conic program

$$\begin{aligned} \min_x \quad & c^T x \\ \text{s.t.} \quad & Ax = b \\ & D(x) + d \in K \end{aligned} \tag{9}$$

$D$  a linear mapping,  $K$  a closed convex cone.

- Very similar to an LP

## Relations

$$LP \subset QP \subset SOCP \subset SDP \subset CP(\text{Conic Programming})$$

## Duality

### Introduction

- Suppose we want to *Lower bound* our convex program
- Find  $B \leq \min_x f(x)$ ,  $x \in C$ .

**Example:**

$$\begin{array}{ll} \min_{x,y} & x + y \\ \text{s.t.} & x + y \geq 2 \\ & x, y \geq 0 \end{array} \tag{10}$$

- What is  $B$ ?

### Harder

**Example:**

$$\begin{array}{ll} \min_{x,y} & x + 3y \\ \text{s.t.} & x + y \geq 2 \\ & x, y \geq 0 \end{array} \tag{11}$$

- What is  $B$ ?

### Why?

**Example:**

$$\begin{array}{ll} \min_{x,y} & x + 3y \\ \text{s.t.} & x + y \geq 2 \\ & x, y \geq 0 \end{array} \iff \begin{array}{ll} \min_{x,y} & (x + y) + 2y \\ \text{s.t.} & x + y \geq 2 \\ & x, y \geq 0 \end{array} \tag{12}$$

- What is  $B$ ?

### Harderer

**Example:**

$$\begin{array}{ll} \min_{x,y} & px + qy \\ \text{s.t.} & x + y \geq 2 \\ & x, y \geq 0 \end{array} \tag{13}$$

- What is  $B$ ?

## Solution

$$\begin{array}{ll}
 \min_{x,y} & px + qy \\
 \text{s.t.} & x + y \geq 2 \\
 & x, y \geq 0
 \end{array}
 \iff
 \begin{array}{ll}
 \min_{x,y} & px + qy \\
 \text{s.t.} & ax + ay \geq 2a \\
 & bx, cy \geq 0 \\
 & a, b, c \geq 0
 \end{array}
 \quad (14)$$

- Adding implies

$$(a + b)x + (a + c)y \geq 2a$$

- Set  $p = (a + b)$  and  $q = (a + c)$  we get that  $B = 2a$

## Better

- We can make this lower bound bigger by maximizing:

$$\begin{array}{ll}
 \max_{a,b,c} & 2a \\
 \text{s.t.} & a + b = p \\
 & a + c = q \\
 & a, b, c \geq 0
 \end{array}
 \quad (15)$$

- This is the **Dual** of the **Primal** LP

$$\begin{array}{ll}
 \min_{x,y} & px + qy \\
 \text{s.t.} & x + y \geq 2 \\
 & x, y \geq 0
 \end{array}
 \quad (16)$$

- Note that the number of Dual variables (3) is the number of Primal constraints

## General LP

$$\begin{array}{ll}
 \text{(P)} & \text{(D)} \\
 \min_x & c^\top x \\
 \text{s.t.} & Ax = b \\
 & Gx \leq h
 \end{array}
 \iff
 \begin{array}{ll}
 \max_{u,v} & -b^\top u - h^\top v \\
 \text{s.t.} & -A^\top u - G^\top v = c \\
 & v \geq 0
 \end{array}
 \quad (17)$$

## Exercise

### Alternate derivation

$$\begin{array}{ll}
 \min_x & c^\top x \\
 \text{s.t.} & Ax = b \\
 & Gx \leq h
 \end{array}
 \quad (18)$$

- Suppose that some  $x$  is feasible.
- Then, for that  $x$ ,

$$c^\top x \geq c^\top x + u^\top (Ax - b) + v^\top (Gx - h) =: L(x, u, v).$$

as long as  $v \geq 0$  and  $u$  is anything.

- We call  $L(x, u, v)$  the **Lagrangian**.

Now, suppose  $C$  is the feasible set, and  $f^*$  is the optimum

$$f^* \geq \min_{x \in C} L(x, u, v) \geq \min_x L(x, u, v) =: g(u, v)$$

- We call  $g(u, v)$  the **Lagrange Dual Function**

## Weak duality

Consider the generic (primal) convex program

$$\begin{aligned} \min_x \quad & f(x) \\ \text{s.t} \quad & l_i(x) = 0 \\ & h_i(x) \leq 0 \end{aligned} \tag{19}$$

- For feasible  $x, v \geq 0$

$$f(x) \geq f(x) + u^\top h(x) + v^\top l(x) \geq \min_x L(x, u, v) = g(u, v).$$

- Therefore,

$$f^* \geq \max_{\forall u, v \geq 0} g(u, v) = g^*.$$

- This is **weak duality**.
- Note that the Dual Program is always convex even if  $P$  is not (pointwise max of linear functions)

## Strong duality

$$f^* = g^*$$

- Sufficient conditions for strong duality: **Slater's conditions**
- If  $P$  is convex and there exists  $x$  such that for all  $i, h_i(x) < 0$  (strictly feasible), then we have strong duality. (Extension: strict inequalities for  $i$  when  $h_i$  not affine.)
- Sufficient conditions for strong duality of an LP: strong duality if either  $P$  or  $D$  is feasible. (Dual of  $D = P$ )

## Example

Dual for Support Vector Machine

$$\begin{aligned} \text{(P)} \quad & \min_{\xi, \beta, \beta_0} \quad \frac{1}{2} \|\beta\|_2^2 + C\mathbb{K}^\top \xi \\ \text{s.t} \quad & \xi_i \geq 0 \\ & y_i(x_i^\top \beta + \beta_0) \geq 1 - \xi_i \\ \text{(D)} \quad & \max_w \quad -\frac{1}{2} w^\top \tilde{X}^\top \tilde{X} w + \mathbb{K}^\top w \\ \text{s.t} \quad & 0 \leq w \leq C\mathbb{K} \\ & w^\top y = 0 \end{aligned} \tag{20}$$

where  $\tilde{X} = \text{diag}(y)X$ .

- $w = 0$  is Dual feasible.
- Rewrite  $0 \leq w \leq C\mathbb{K}$  as  $w > 0, \quad w_i - C \leq 0$ .
- Thus,  $w = 0$  is strictly feasible.
- We have strong duality by Slater's conditions.

## KKT conditions

1. Stationarity:  $0 \in \partial(f(x) + u^T h(x) + v^T l(x))$ : For some pair  $(u, v)$ ,  $x$  minimizes the Lagrangian.
2. Complementary slackness:  $u_i h_i(x) = 0$ ,  $\forall i$
3. Primal feasibility:  $h_i(x) \leq 0$ ,  $l_i(x) = 0$
4. Dual feasibility:  $u \geq 0$

**Theorem:** Solutions  $x^*$  and  $(u^*, v^*)$  Primal-Dual optimal and  $f^* = g^*$ , then they satisfy the KKT conditions.

**Theorem:** Solutions  $x^*$  and  $(u^*, v^*)$  that satisfy the KKT conditions are Primal-Dual optimal.

### Example (SVM cont.)

1. Stationarity:  $w^\top y = 0$ ,  $\beta = w^\top \tilde{X}$ ,  $w = C1 - v$
2. CS:  $v_i \zeta_i = 0$ ,  $w_i(1 - \zeta_i - y_i(x_i^\top \beta + \beta_0)) = 0$
3. Clear.
4. Clear.

## Constraints and Lagrangians

When are the two following forms equivalent?

constrained form (C):

$$\begin{aligned} \min f(x) \\ \text{s.t. } h(x) \leq t \end{aligned}$$

Lagrangian form (L):

$$\min f(x) + \lambda h(x)$$

When C is strictly feasible, strong duality holds. So there exists  $\lambda$  such that for each  $x$  that solves C those  $x$  minimize L.

Now, if  $x^*$  solves L, then KKT condition for C hold by taking  $t = h(x^*)$  and so  $x^*$  is a solution of C.

## Algorithms

### First order methods

For simplicity, consider unconstrained optimization

$$\min_x f(x) \tag{21}$$

assume  $f$  is convex and differentiable

#### Gradient descent

- Choose  $x^{(0)}$
- Iterate  $x^{(k)} = x^{(k-1)} - t_k \nabla f(x^{(k-1)})$
- Stop sometime

Why?

- Taylor expansion

$$f(y) \approx f(x) + \nabla f(x)^\top (y - x) + \frac{1}{2} (y - x)^\top H(y - x) \tag{22}$$

- replace  $H$  with  $1/t$
- Choose  $y = x^+$  to minimize the quadratic approximation

## What $t$ ?

What to use for  $t_k$ ?

### Fixed

- Only works if  $t$  is exactly right
- Usually does not work

### Sequence

$$t_k \quad s.t. \quad \sum_{k=1}^{\infty} t_k = \infty, \quad \sum_{k=1}^{\infty} t_k^2 < \infty \quad (23)$$

**Backtracking line search** At each iteration choose best  $t$

1. Set  $0 < \beta < 1, 0 < \alpha < \frac{1}{2}$
2. At each  $k$ , while

$$f\left(x^{(k)} - t\nabla f(x^{(k)})\right) > f(x^{(k)}) - \alpha t \left\| \nabla f(x^{(k)}) \right\|_2^2 \quad (24)$$

set  $t = \beta t$  (shrink  $t$ )

3.  $x^{t+1} = x - t\nabla f(x_t)$

Exact line search

- Backtracking approximates this
- At each  $k$ , solve

$$t = \arg \min_{s \geq 0} f(x^{(k)} - s\nabla f(x^{(k)}))$$

- Usually can't solve this.

## Convergence

If  $\nabla f$  is Lipschitz, use fixed  $t$

1. GD converges at rate  $O(1/k)$
2.  $\epsilon$ -optimal in  $O(1/\epsilon)$  iterations

If  $f$  is strongly convex as well

1. GD converges at rate  $O(c^k)$  ( $0 < c < 1$ ).
2.  $\epsilon$ -optimal in  $O(\log(1/\epsilon))$  iterations

We call this second case “linear convergence” because it’s linear on the log scale.

## Stochastic Gradient Descent

- Workhorse in Neural Networks
- Suppose

$$f(x) = \frac{1}{m} \sum_{i=1}^m f_i(x)$$

- GD would use

$$x^{(k)} = x^{(k-1)} - \frac{t}{m} \sum_{i=1}^m \nabla f_i(x^{(k-1)})$$

- SGD uses

$$x^{(k)} = x^{(k-1)} - t \nabla f_{i_k}(x^{(k-1)})$$

$i_k \in \{1, \dots, m\}$  is an index chosen at time  $k$ .

Standard choices for  $i_k$

1. Draw  $i_k \sim \text{Unif}(\{1, \dots, m\})$ .
2. Set  $i_k = 1, \dots, m, 1, \dots, m, 1, \dots, m, \dots$

Most frequently update “mini-batches”. Why?

1. Convergence rates are slower for SGD than GD.
2. Batches improves this.
3. SGD is computationally more efficient in per-iteration cost, memory
4. Efficient when far from the optimum, less good close to the optimum (but statistical properties don't care when you're close)

## Subgradient descent

What happens when  $f$  isn't differentiable?

A **subgradient** of convex  $f$  at a point  $x$  is any  $g$  such that

$$f(y) \geq f(x) + g^\top(y - x) \quad \forall y$$

- Always exists
- $f$  differentiable  $\Rightarrow g = \nabla f(x)$  (unique)
- Just plug in the subgradient in GD
- $f$  Lipschitz gives  $O(1/\sqrt{k})$  convergence

## Example (LASSO)

$$\min_{\beta} \frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\beta\|_1$$

- Subdifferential (the set of subgradients)

$$\begin{aligned} g(\beta) &= -X^T(y - X\beta) + \lambda \partial \|\beta\|_1 \\ &= -X^T(y - X\beta) + \lambda v \\ v_i &= \begin{cases} \{1\} & \text{if } \beta_i > 0 \\ \{1\} & \text{if } \beta_i < 0 \\ [-1, 1] & \text{if } \beta_i = 0 \end{cases} \end{aligned}$$

So  $\text{sign}(\beta) \in \partial \|\beta\|_1$

- From KKT (stationarity)

$$X^T(y - X\beta) = \lambda v$$

$$X_i^T(y - X\beta) = \lambda v_i$$

- Therefore

$$|X_i^T(y - X\beta)| = \lambda \Rightarrow \beta_i \neq 0$$

$$|X_i^T(y - X\beta)| < \lambda \Rightarrow \beta_i = 0$$

- Checking the KKT conditions underlies the LARS algorithm

## Proximal gradient descent

Suppose  $f$  is **decomposable**

$$f(x) = g(x) + h(x)$$

- We assume  $g$  is convex and differentiable, but  $h$  is convex only
- Approximate  $g$  only (via Taylor with approximate Hessian)

$$\begin{aligned} x^+ &= \arg \min_z g(x) + \nabla g(x)^\top (z - x) + \frac{1}{2t} \|z - x\|_2^2 + h(z) \\ &= \arg \min_z \frac{1}{2t} \|z - (x - t\nabla g(x))\|_2^2 + h(z) \end{aligned}$$

- The first part keeps us close to the gradient update for  $g$ , but still minimize over  $h$ .
- Define

$$\text{prox}_t(x) := \arg \min_z \frac{1}{2t} \|x - z\|_2^2 + h(z)$$

- The prox operator depends only on  $h$ , not  $g$
- Easily solvable for many  $h$
- Update becomes

$$x^{(k)} = \text{prox}_{t_k} \left( x^{(k-1)} - t_k \nabla g(x^{(k-1)}) \right)$$

## Example (LASSO)

$$\min_{\beta} \underbrace{\frac{1}{2} \|y - X\beta\|_2^2}_g + \underbrace{\lambda \|\beta\|_1}_h$$

$$\begin{aligned} \text{prox}_t(\beta) &= \arg \min_z \|z - \beta\|_2^2 + \lambda \|z\|_1 \\ &=: S_{\lambda t}(\beta) \\ S_{\tau}(\beta) &= \text{sign}(\beta)(|\beta| - \tau)_+ \end{aligned}$$

So the update becomes:

1.  $\beta \leftarrow \beta + tX^\top(y - X\beta)$
2.  $\beta \leftarrow S_{\lambda t}(\beta)$

This is called “Iterative soft thresholding” (ISTA)

## Projected gradient descent

$$\min_{x \in C} f(x)$$

- Incorporate the constraint into the objective using the indicator function:

$$I_C(x) = \begin{cases} 0 & x \in C \\ +\infty & x \notin C \end{cases}.$$

- Call the indicator  $h$ , and use proximal GD
- Now  $\text{prox}_t(x) = \arg \min_{z \in C} \|z - x\|_2^2$
- This is just the Euclidean projection onto  $C$

So the update becomes:

1. Use GD on  $f$
2. Project onto  $C$

## Dual methods

### Dual (sub)gradient ascent/descent

Primal problem:

$$\min_x f(x) \quad \text{s.t.} \quad Ax = b.$$

Dual is

$$\max_u -f^*(-A^\top u) + b^\top u,$$

where  $f^*$  is the **conjugate** of  $f$ .

- Let  $g(u) := f^*(-A^\top u) - b^\top u$ .
- Our goal is to minimize  $g(u)$ .
- The subdifferential is given by

$$\partial g(u) = A\partial f^*(-A^\top u) - b^\top u,$$

but if  $x \in \arg \min_z L(z, u)$  then  $\partial g(u) = Ax - b$ .

- We may solve this as follows:
  1. guess initial  $u^{(0)}$
  2. choose  $x^{(k)} \in \arg \min_x f(x) + (u^{(k-1)})^\top Ax$
  3. Update  $u^{(k)} = u^{(k-1)} + t_k (Ax^{(k)} - b)$

Formally: if  $f$  is strictly convex then

1. conjugate  $f^*$  is differentiable
2. procedure is dual gradient ascent
3.  $x^{(k)}$  is the unique minimizer

We can choose  $t_k$  as before and apply proximal methods (or acceleration).

### Decomposable dual

$$\min_x \sum_{i=1}^m f_i(x_i) \quad \text{s.t.} \quad Ax = b$$

standard minimization decomposes into  $x^+$ , which is equivalent to solving separately for each  $x_i$ :

$$x_i^+ \in \arg \min_{x_i} f_i(x_i) + u^\top A_i x_i.$$

So we can iterate:

$$\begin{aligned} x_i^{(k)} &\in \arg \min_{x_i} f_i(x_i) + (u^{(k-1)})^\top A_i x_i \\ u^{(k)} &= u^{(k-1)} + t_k \left( \sum_{i=1}^m A_i x_i^{(k)} - b \right) \end{aligned}$$

- Strong duality holds in this particular example since we have no inequality constraints.
- If the constraints are inequalities, i.e.  $Ax \leq b$ , we make a slight modification to  $u^{(k)}$ :

$$u^{(k)} = \left( u^{(k-1)} + t_k \left( \sum_{i=1}^m A_i x_i^{(k)} - b \right) \right)_+$$

- Updates can be parallelized.

## Augmented Lagrangian

- For dual ascent to work ( $\rightarrow g^*$ ), we need  $f$  “nice”
- To achieve strong duality (primal optimality) the program must also satisfy one of the conditions mentioned earlier (e.g. Slater’s condition).

We can alter the problem to enforce strong convexity

- Use  $\min_x f(x) + \frac{\rho}{2} \|Ax - b\|_2^2$  s.t.  $Ax = b$ .
- The objective is strongly convex if  $A$  has full column rank.
- Dual gradient ascent then becomes

$$\begin{aligned} x^{(k)} &= \arg \min_x f(x) + (u^{(k-1)})^\top Ax + \frac{\rho}{2} \|Ax - b\|_2^2 \\ u^{(k)} &= u^{(k-1)} + \rho(Ax^{(k-1)} - b) \end{aligned}$$

- Replacing the step size  $t_k$  with  $\rho$  gives better convergence properties than the original DGA.
- But introducing the norm kills decomposability (if we had it), no parallelization
- $\rho$  balances primal feasibility with a small objective
- larger  $\rho$  deemphasizes objective but forces  $x^{(k)}$  toward primal feasibility

## Alternating Direction Method of Multipliers (ADMM)

$$\min_{x,z} f(x) + g(z) \quad \text{s.t.} \quad Ax + Bz = c$$

Add  $\frac{\rho}{2} \|Ax + Bz - c\|_2^2$  to the objective, penalizing infeasibility:

$$L_\rho(x, z, u) = f(x) + g(z) + u^\top (Ax + Bz - c) + \frac{\rho}{2} \|Ax + Bz - c\|_2^2$$

Iteratively update:

$$\begin{aligned} x^{(k)} &= \arg \min_x L_\rho(x, z^{(k-1)}, u^{(k-1)}) \\ z^{(k)} &= \arg \min_z L_\rho(x^{(k-1)}, z, u^{(k-1)}) \\ u^{(k)} &= u^{(k-1)} + \rho(Ax^{(k-1)} + Bz^{(k-1)} - c) \end{aligned}$$

Properties of ADMM (some of which do not require  $A$  and  $B$  to be full rank):

1.  $Ax^{(k)} + Bz^{(k)} - c \rightarrow 0$  as  $k \rightarrow \infty$  (primal feasibility)
2.  $f^{(k)} + g^{(k)} \rightarrow f^* + g^*$  (primal optimality)
3.  $u^{(k)} \rightarrow u^*$  (dual solution)
4. doesn’t necessarily give  $x^{(k)} \rightarrow x^*$  and  $z^{(k)} \rightarrow z^*$

The exact convergence rate is unknown, but empirically seems close to  $O(1/\epsilon)$ .

## Example (LASSO)

$$\min_{\beta} \frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\alpha\|_1 \quad \text{s.t.} \quad \alpha = \beta$$

ADMM update (compare with ridge regression):

$$\begin{aligned}\beta^{(k)} &= (X^T X + \rho I)^{-1} (X^T y + \rho(\alpha^{(k-1)} - w^{(k-1)})) \\ \alpha^{(k)} &= S_{\lambda/\rho}(\beta^{(k)} + w^{(k-1)}) \\ w^{(k)} &= w^{(k-1)} + \beta^{(k)} - \alpha^{(k)}\end{aligned}$$

Issues with ADMM:

- How to choose  $\rho$ .
- Different ADMM formulations of the problem may have different convergence properties.

## Coordinate descent

- Works well with LASSO.
- If  $f(x) = g(x) + \sum_{i=1}^n h_i(x_i)$  where  $g$  is convex and differentiable,  $h$  merely convex
- Then:

1. Guess  $x^{(0)}$ .

2. Update according to:

$$\begin{aligned}x_1^{(k)} &\in \arg \min_{x_1} f(x_1, x_2^{(k-1)}, \dots, x_n^{(k-1)}) \\ x_2^{(k)} &\in \arg \min_{x_2} f(x_1^{(k)}, x_2, \dots, x_n^{(k-1)}) \quad (\text{minimize over whole vector or block}) \\ &\vdots\end{aligned}$$

## Example (LASSO)

This is what GLMNET does

$$\min_{\beta} \frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\beta\|_1$$

- $\|\beta\|_1 = \sum_{i=1}^p |\beta_i|$
- Iterate over  $p$

$$\beta_i \leftarrow S_{\lambda/\|X_i\|_2^2} \left( \frac{X_i^T (y - X_{-i} \beta_{-i})}{X_i^T X_i} \right)$$

- Comes from taking derivative of objective wrt  $\beta_i$
